Overview of Environmental and Hydrogeologic Conditions at Cold Bay, Alaska

By Wendy A. Rice and Eppie V. Hogan

ABSTRACT

Cold Bay is near the southern tip of the Alaska Peninsula and has a maritime climate with mild winters and cool summers that affect the hydrology of the area. The city of Cold Bay and the Federal Aviation Administration facility obtain their drinking water from unconfined ground-water sources. Ground-water contamination and possible flooding of local communities may affect the quality of drinking water. The Federal Aviation Administration owns or operates airway support facilities at Cold Bay. The Federal Aviation Administration needs information on environmental and hydrogeologic conditions when evaluating options for environmental compliance and possible remediation at these facilities. This report describes the climate, vegetation, geology, ground-water and surface-water hydrology, and flood potential of the Cold Bay area.

INTRODUCTION

The Federal Aviation Administration (FAA) owns and (or) operates airway support and navigational facilities throughout Alaska. At many of these facilities, fuels and potentially hazardous materials such as solvents, polychlorinated biphenyls (PCB's), and pesticides may have been used and (or) disposed of. To determine if environmentally hazardous materials have been spilled or disposed at the facilities, the FAA is conducting environmental studies mandated by the Comprehensive Environmental Response, Compensation, and Liability Act and the Resource Conservation and Recovery Act. To complete these more comprehensive environmental studies, the FAA requires information on the hydrology and geology of areas surrounding the facilities. This report, the product of compilation, review, and summary of existing hydrologic and geologic data by the U.S. Geological Survey (USGS) in cooperation with the FAA, describes general hydrogeologic and other environmental conditions near Cold Bay, Alaska.

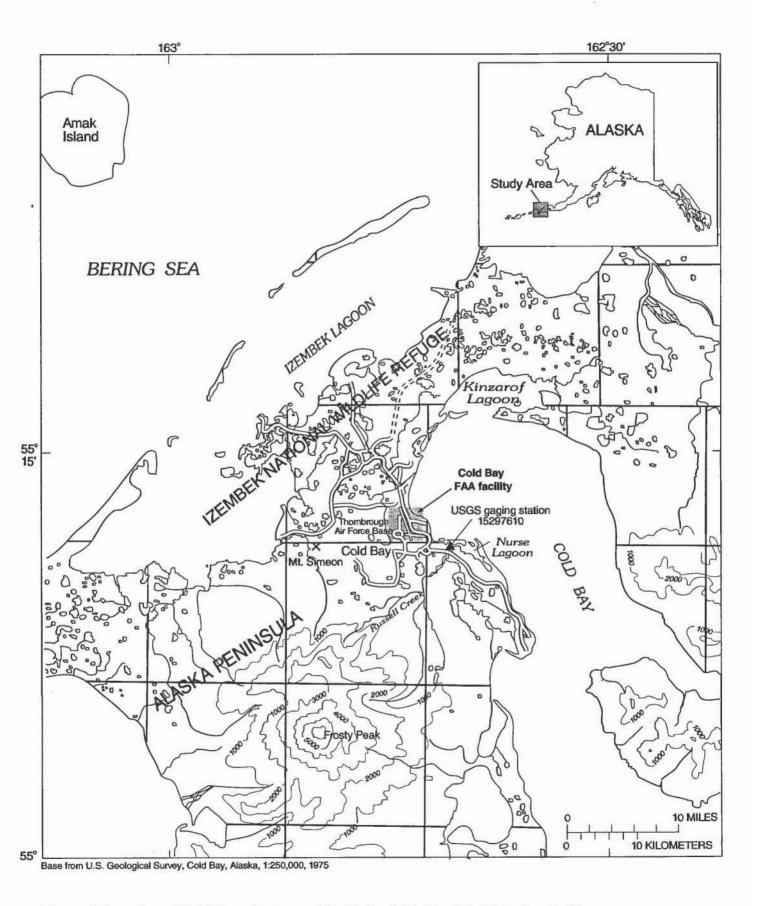

Figure 1. Location of Cold Bay, Alaska and the Federal Aviation Administration facility.

BACKGROUND

Location

The FAA facility at Cold Bay is on the Alaska Peninsula at approximate lat 55 12' N. and long 162°41' W. (fig. 1). Cold Bay is in the northern part of the Izembek National Wildlife Refuge, about 1,000 km southwest of Anchorage and 300 km northeast of Unalaska. Cold Bay has a topography similar to the nearby Aleutian Islands. The topography is characterized by a rolling, treeless tundra that contains several lakes. The City of Cold Bay is on the northwestern shore of Cold Bay, an embayment of the Pacific Ocean. The embayment is about 14 km across at its widest point and protrudes inland about 40 km. The dominant physical feature near Cold Bay is Frosty Peak, a 1,920-meter-high volcanic mountain that is due south of the city.

History and Socioeconomics

The Cold Bay area remained largely undeveloped until the onset of World War II. The Japanese occupation of the outer Aleutian Islands spurred the construction of a series of strategic American bases, including Fort Randall, a large base built on the shores of Cold Bay in 1942 (Environmental Services Ltd., 1982). Since then, the population of Cold Bay has risen and fallen, depending largely on the airport's utilization (Environmental Services Ltd., 1982).

In 1960, the population of Cold Bay was 86; in 1970 it was 261; in 1980 it was 226; and in 1993 the population was 154 (Environmental Services Ltd., 1982; U.S. Army Corps of Engineers, 1993). About 10 percent of the people are American Indian, Eskimo, or Aleut, about 84 percent are Caucasian, about 4 percent are African-American or Asian/Pacific Islander, and 2 percent are of other ethnic origin (Environmental Services Ltd., 1982).

The population of Cold Bay is transient and depends largely on the airport and government for employment. The city is in advantageous proximity to many Bering Sea resources and dramatic changes in the economic base of the community could result from the development of oil and gas resources on the outer continental shelf and (or) the fishing industry. If oil and gas development occurs, underwater pipelines from the nearby St. George Basin and the Northern Aleutian Shelf might terminate in Cold Bay (Braham and others, 1981; Sallenger and Dingler, 1979). In this event, a port facility would be needed to transfer the oil and gas to waiting tankers. The additional development of fisheries in the Cold Bay area also may enhance the economic base of the city.

FAA Facilities

The Cold Bay FAA facility consists of an 87-hectare installation in the city of Cold Bay (fig. 1). The facility was constructed in 1958-59 as an extension of the military's Distant Early Warning (DEW) line into the Aleutian Islands. Detailed lists of FAA facilities and potential sources of environmental contamination can be found in an Environmental Compliance Investigation Report (ECIR) by Ecology and Environment, Inc., (1992).

PHYSICAL SETTING

Climate

Cold Bay lies in the maritime climate zone (Hartman and Johnson, 1984). Climatic conditions are influenced by the Bering Sea and the North Pacific and are characterized by small temperature variations, high humidity, heavy precipitation, and frequent foggy periods. Cold Bay has one of the highest percentages of cloud cover in the United States. Cyclonic storms with high winds, low ceilings, and poor visibility occur frequently. Mountains rise more than 1,800 m, about 15 km south-southwest of Cold Bay. These mountains provide protection from approaching south-westerly and southeasterly winds and precipitation. The mean annual temperature for 1950-87 for Cold Bay is 3.4 °C. Mean monthly temperatures range from an August mean maximum of 13.1 °C to a February mean minimum of -5.2 °C (Leslie, 1989; table 1). Mean annual precipitation is about 910 mm with most rainfall occurring in October and November. Mean annual snowfall is about 1,600 mm.

¹Record maximum, 25.0°C, July 1960.

Vegetation

The Cold Bay FAA facility is located within a wet tundra ecosystem consisting principally of coastal heath shrub and alder thickets (Viereck and Little, 1972). Wetlands are found in the Izembek National Wildlife Refuge and along the shores of Nurse Lagoon (fig. 1). Typical wetland vegetation includes cotton grass, willow, bur reed, pond weed, and a variety of sedges and grasses. The shoreline near the FAA facility consists of exposed tidal flats and expanses of rocky beach. Beds of eelgrass cover about 70 percent of the local tidal flats.

²Record minimum, -25.0°C, March 1971.

Geology

Most of the landscape in the Cold Bay area was formed in the last 1 to 2 million years as a result of volcanism and glaciation (McLean, 1979). The distribution of volcanic rocks and surficial deposits are indicated on geologic maps of the area by Wilson and others (1992).

Volcanic rocks of Quaternary age are mainly of andesite, dacite, and basalt composition and occur as volcanic breccia and lahar, and debris-flow deposits (Wilson and others, 1992). These rocks are confined to the area around Frosty Peak (fig. 1) and are not exposed near the FAA facility. Most of the volcanic rocks in the area were formed by volcanic activity on Amak Island, Frosty Peak, Mount Simeon, (fig. 1) and Mount Dutton (Waldron, 1961; Wood and Kienle, 1990). Ash and basalt deposits are assumed to have been deposited by activity on Amak Island and Frosty Peak (Waldron, 1961). The Amak volcano has been active as recently as 1796; the Cold Bay volcanic center is extinct (Wood and Kienle, 1990). Volcanic rocks of Quaternary age overlie basalt flows of Tertiary age from Mount Simeon. These crystalline basalt flows dip towards the southwest toward Frosty Peak and are rarely exposed because of glacial drift cover. The absolute age of the Mount Simeon basalt flows is unknown (Waldron 1961). Mount Dutton, which is about 25 km west of Cold Bay, has no historic eruptive activity; however, in 1984-85 and in 1988, swarms of earthquake occurred beneath the volcano (Wood and Kienle, 1990).

Surficial deposits are of glacial, volcanic, and coastal origin (Wilson and others, 1992). Moraines and other glacial deposits cover most of the lowland near Cold Bay. These deposits are exposed in nearby bluffs and consist of mixed sand and gravel. A terminal moraine near the FAA facility forms an arcuate ridge complex around the northern perimeter of Cold Bay. Rock fragments within the glacial deposits are mostly volcanic (Waldron, 1961). The thickness of glacial drift is unknown. Fine volcanic ash was deposited on exposed glacial deposits as evidenced by several layers of dark reddish-brown and black coarse-grained ash that are as much as 13 cm thick (Waldron, 1961). Coastal deposits are composed of interlayered marine and alluvial deposits with grain sizes ranging from mud to boulders. Wave erosion on the Pacific shores of Cold Bay has resulted in the formation of spits and bars. Both Kinzarof Lagoon, at the head of Cold Bay, and Nurse Lagoon, southeast of the FAA facility, were formed by the deposition of sand spits (Waldron, 1961). No permafrost exists in the area of Cold Bay (Ferrians, 1965).

The lithology of sediments from a 41-meter-deep well drilled at the FAA facility in September 1963 indicates that the following deposits are present in the subsurface: muck to a depth of 1.2 m; thawed muck, gravel, and sand to a depth of 2.1 m; clay, gravel, and rocks to 25 m; clay, gravel, sand, and water to 33 m; hard pan and clay to 34 m; and gravel, clay, sand, and water to 41 m below land surface (appendix 1).

Earthquakes

Cold Bay lies within the circum-Pacific seismic belt that rims the north Pacific Ocean. The area is traversed by the Aleutian Trough and many smaller faults. In recent years, several earthquakes with Richter magnitudes greater than 7 have been recorded along these fault systems (Brower and others, 1977; Stephens and others, 1986).

HYDROLOGY

Ground Water

In the Cold Bay area, ground water generally exists under unconfined conditions within the sand and gravel lenses associated with till (appendix 1). In the underlying volcanic bedrock, ground water could possibly be obtained from secondary openings such as fractures and joints (Jones and others, 1978). However, no data are available to support this hypothesis. Ground water is recharged by infiltration of rainfall and snowmelt. It is assumed to flow from south to north along the slopes of Frosty Peak, discharging into Cold Bay and (or) the Izembek Lagoon.

At least 10 wells have been drilled near the Cold Bay FAA facility, and another 4 wells were drilled along Russell Creek (appendix 1; CH2M Hill, 1977). The wells drilled near the facility range in depth from 17 to 39 m below land surface. Ground water was reached at depths ranging from 2 to 26 m below land surface (appendix 1). In a 38-meter-deep well at the facility, ground water was reached at a depth of 19 m below land surface. After 2 hours of pumping at a rate of 0.9 L/s, drawdown in this well was 8.8 m (appendix 1). Recovery-time data are not available. The four wells drilled near Russell Creek ranged in depth from 25 to 31 m below land surface (appendix 1; CH2M Hill, 1977). Water was reached at depths ranging from 7 to 15 m below land surface. The largest recorded yields from wells near Cold Bay were between 6.0 and 8.2 L/s (CH2M Hill, 1977; U.S. Army Corps of Engineers, 1979).

Surface Water

There are no large rivers near the city of Cold Bay. The nearest stream of significant size is Russell Creek, about 4 km to the southwest. Russell Creek originates on the slopes of Frosty Peak, generally flows from southwest to northeast, and drains into Cold Bay. The creek is about 20 km long and has a gradient averaging 180 m/km near its head and 120 m/km near its mouth. Russell Creek drains an area of about 65 km² upstream from the USGS streamflow-gaging station 15297610, Russell Creek near Cold Bay (fig. 1), where a record of discharge was collected from 1981 to 1986. The flow of Russell Creek varies seasonally. The lowest flows occur during March and April when mean flow is about 3.5 m³/s (table 2, this report; U.S. Geological Survey, 1987). Because of increased snowmelt and rainfall, the highest flows in Russell Creek occur from July to December. Mean flow during this period ranges from 8.8 to 11.4 m³/s (table 2, this report; U.S. Geological Survey, 1987). Mean annual runoff near Cold Bay averages 0.1 (m³/s)/km² (U.S. Geological Survey, 1987).

Table 2. Mean monthly flow at streamflow-gaging station 15297610 Russell Creek near Cold Bay, water years 1981–86 [Values in cubic meters per second]

	Oct.	Nov.	Dec.	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.
Mean	9.1	9.6	8.9	5.9	4.9	3.5	3.5	5.7	7.6	9.9	8.8	11.4
Maximum	14.6	15.0	15.5	9.0	7.7	4.3	5.8	8.5	9.3	15.0	10.9	14.8
Minimum	6.7	7.3	4.8	2.9	2.8	2.1	2.3	3.9	6.3	7.4	7.5	6.2

Small glacial lakes, typically less than 0.5 km² in size, cover the landscape near the FAA facility and surrounding lowlands of Cold Bay. The lakes generally are shallow and typically freeze for 2 to 3 months beginning in mid-January (Selkregg, 1976).

Tides

A two-layered estuarine-circulation system is common in the coastal areas of the Alaska Peninsula. This phenomenon is seasonal and begins during the spring thaw with an increase in freshwater discharge. The fresh water flows seaward along the surface and is replaced by saline water that intrudes at greater depths. During the fall and winter, storms and reduced runoff combine to thoroughly mix the layers and destroy the system. Tidal fluctuations also may contribute to the mixing and circulation of fresh and salt water. The diurnal tide range in Cold Bay averages 2.2 m and is the difference in height between mean higher high water and lower low water in a single day (Brower and others, 1977). The maximum predicted tide at Cold Bay is 3.4 m above mean sea level. The minimum predicted tide is -0.7 m below mean sea level (Brower and others, 1977).

Flooding

Cold Bay has a low flood-hazard rating; however, it is subject to some degree of flooding from storm-surge or tsunami waves (U.S. Army Corps of Engineers, 1993). Tsunami waves commonly are generated by seismic activity and are capable of traveling great distances across water striking shore areas with destructive effect. Storm-surge waves also can affect low-lying coastal areas, but have less potential to travel inland because of their reduced wave velocity. Brower and others (1977) describe return periods for maximum significant wave heights for coastal areas in Alaska. A 100-year-wave more than 20 m high is possible at Cold Bay (table 3).

Table 3. Annual maximum waves for selected return periods near Cold Bay

Return period (years)	Maximum significant wave (meters)			
5	13.0			
10	14.5			
25	17.5			
50	19.5			
100	22.0			

Overbank flooding of stream channels on the lower Alaska Peninsula may occur during the months from July to October and is primarily the result of intense rainfall augmented by melting snow. Overbank flooding also may result from the rapid melting of snow and ice during volcanic eruptions (Selkregg, 1976; Jones and Fahl, 1994). On October 22, 1981, rainfall runoff caused a maximum stream discharge of 170 m³/s at the USGS streamflow-gaging station 15297610, Russell Creek near Cold Bay (Jones and Fahl, 1994). Flooding, however, was not reported in the Cold Bay area at this time.

DRINKING WATER

Present Drinking-Water Sources

Ground water is the principal drinking-water source for Cold Bay and typically is found in unconsolidated deposits at depths between 2 and 26 m below land surface. The aquifer is unconfined and shallow, and thus it is vulnerable to contamination. Drinking water for Cold Bay is obtained from two wells equipped with submersible pumps and is stored in four holding tanks. Two tanks hold 56,700 L of water that is chlorinated and distributed by pipe to residents, and the remaining two tanks hold 94,500 L of water that is held in reserve for fire fighting (Environmental Services Ltd., 1982). Average daily water use in Cold Bay ranges from 76,000 to 113,600 L/d (Environmental Services Ltd, 1982).

In general, the quality of ground water on the lower Alaska Peninsula and in the Aleutian Islands is good (Selkregg, 1976). Most ground-water samples contained total dissolved solids of less than 200 mg/L. Although some ground water may be corrosive to metals, most water is acceptable for domestic, agricultural, and industrial uses. Existing data indicate that most inorganic constituents of sampled ground-water sources satisfy the Class A regulations of the Alaska Department of Environmental Conservation (ADEC) and the U.S. Environmental Protection Agency (USEPA) (appendix 2; U.S. Army Corps of Engineers, 1979; Salvato, 1992; CH2M Hill, 1977). The quality of water from wells drilled near Russell Creek was reported to be excellent (appendix 2; CH2M Hill, 1977; table 4, this report).

Table 4. Selected chemical analyses of water from wells near Cold Bay, Alaska

Constituent	Concentration, in milligrams per liter	Constituent	Concentration, in milligrams per liter
Dissolved solids, total	90	Nitrate	<.8
Alkalinity, as CaCO ₃	18	Fluoride	<3.2
Chloride	<2.9	Suspended solids, total	ব
Iron	<.1		

Alternative Drinking-Water Sources

Drinking-water alternatives for the FAA facility and the city of Cold Bay include Russell Creek and many small lakes. During the 1950's and 1960's, personnel stationed at the Thornbrough U.S. Air Force Base (fig. 1) used a small lake as a drinking-water source (Feulner, 1966). Chemical analyses of the lake indicated that concentrations of major ions and water properties were within current ADEC and USEPA drinking-water regulations (appendix 2; Feulner, 1966). The quality and quantity of the water in other lakes near Cold Bay are unknown.

The flow in Russell Creek represents an abundant source of drinking water for the area. During months of low discharge in March and April, mean flow of Russell Creek is about 3.5 m³/s (table 2; U.S. Geological Survey, 1987), which is greater than the estimated water use of the city. Major ions, nutrients, dissolved metals, and other water properties in Russell Creek are within current ADEC and USEPA drinking-water regulations (table 5; appendix 2; U.S. Geological Survey, 1983).

Table 5. Selected chemical analyses of water from Russell Creek near Cold Bay, Alaska, water year 1982 [Concentration in milligrams per liter, unless otherwise noted. µS/cm at 25 °C, microsiemen per centimeter at 25 °C; µg/L, microgram per liter]

Constituent or property	Concentration	Constituent or property	Concentration	
Specific conductance (µS/cm at 25°C)	32–62	Sulfate (SO ₄)	< 5.0	
pH (units)	6.1–7.5	Chloride (Cl)	5.4-11	
Temperature (°C)	2.0-7.5	Fluoride (Fl)	< 0.1	
Hardness as CaCO ₃ (Ca, Mg)	9–15	Silica (SiO ₂)	9.7–20	
Sodium (Na)	4.0-7.2	Fecal coliform (colonies/100mL)	<1	
Potassium (K)	0.6-1.0	Iron, total (Fe) (µg/L)	220-870	
Bicarbonate (HCO ₃)	7–10	Iron, dissolved (Fe) (µg/L)	15–110	
Carbonate (CO ₃)	0.0			

SUMMARY

Cold Bay's population is transient and depends on the local airport and government jobs for employment. Ground water is the principal drinking-water source and typically is found in unconsolidated deposits at depths ranging from 2 to 26 m below land surface. Water in the unconfined aquifer is currently of acceptable drinking-water quality but because it is shallow, it may be vulnerable to contamination. Russell Creek and many small lakes and ponds represent alternative drinking-water sources.
