CONVERSION FACTORS AND VERTICAL AND HORIZONTAL DATUMS

	Multiply	By	To obtain
foot (ft)		0.3048	meter
mile (mi)		1.609	kilometer
square mile (mi ²)		2.59	square kilometer
gallon (gal)		3.785	liter
gallons per minute (gal/min)		0.06308	liters per second

Vertical Datum:

In this report, "sea level" refers to the National Geodetic Vertical Datum of 1929 (NGVD of 1929), a geodetic datum derived from a general adjustment of the first-order level nets of both the United States and Canada, formerly called Sea Level Datum of 1929.

Horizontal Datum:

The horizontal datum for all locations in this report is the North American Datum of 1927. Multiple reference marks were used from Alaska Department of Transportation and Public Facilities surveys. Global positioning survey instruments were also used to determine horizontal control points.

Ground-Water and Surface-Water Elevations in the University of Alaska Fairbanks Area, 1992-95

By Melanie L. Jackson *and* Michael R. Lilly

Abstract

The U.S. Geological Survey, in cooperation with the University of Alaska Fairbanks, collected water-elevation data at 50 ground-water sites and 11 surface-water sites. These data were collected during 1992 to 1995 to characterize the geohydrology of the University of Alaska Fairbanks area.

INTRODUCTION

The U.S. Geological Survey (USGS), in cooperation with the University of Alaska Fairbanks (UAF), is presently (1996) conducting a cooperative study to characterize the geohydrology of the UAF area, which lies west of and adjacent to the city of Fairbanks (figs. 1 and 2). The UAF study area is about 3 mi² in size and lies partly in the alluvial plain of the Chena and Tanana Rivers and partly on College Hill. University Avenue forms the eastern boundary of the study area, with the Chena River on the south, and the Parks Highway on the west (figs. 1 and 2). College Hill, where the main UAF campus is located, forms the northern boundary of the study area (fig. 2).

Water levels in 50 ground-water wells and at 11 surface-water sites were measured at monthly intervals. In addition, water levels at selected sites were measured at more frequent intervals to monitor short-term changes in ground-water levels caused by rapid stage changes of the Chena and Tanana Rivers. Additional water levels were measured to document the effects of UAF water-supply well pumping on the ground-water system. Ground-water data are maintained in the USGS Ground-Water Site Inventory (GWSI) data base and surface-water data are maintained in the USGS Automatic Data Acquisition and Processing System (ADAPS) data base. This report presents ground-water and surface-water elevation data collected between May 1992 and October 1995.

GEOHYDROLOGIC SETTING

The UAF campus is in the Tanana River Valley on the northern boundary between the alluvial sand and gravel deposits of the Chena Alluvium (Péwé and others, 1976) and the bedrock hills of the Yukon-Tanana Upland (Anderson, 1970). The primary depositional source of the Chena Alluvium is the Tanana River. Sediment facies within the Chena Alluvium are laterally discontinuous, as is typical of deposits from braided rivers (Rust, 1978). The thickness of these deposits is unknown but may be in excess of 500 ft in places (Nelson, 1978). The bedrock hills are part of a metamorphic rock system that forms the Yukon-Tanana Upland. Most wells in the bedrock obtain water from fracture systems that have formed during numerous tectonic events (Nelson, 1978).

Eolian silts of the Fairbanks Loess and reworked silt deposits of the Ready Bullion Formation cover the bedrock hills and grade into alluvial-fan silt deposits and the Chena Alluvium.

Figure 1. Location of Fairbanks, Alaska, and the University of Alaska Fairbanks study area.

The distribution of permafrost in the study area is discontinuous. Geotechnical borings west of the study area at the Parks Highway and Geist Road intersection indicate that permafrost extends from approximately 40 ft below the land surface down to depths greater than 100 ft below the land surface (Alaska Department of Transportation and Public Facilities, 1990). Drillers' logs of wells throughout the study area indicate that the permafrost thickness ranges from 5 to more than 30 ft. UAF water-supply wells located between College Hill and Geist Road are in permafrost-free zones. Péwé and Bell (1974) describe the permafrost distribution in the study area and characterize the ground as containing a moderate to high ice content.

The Tanana River is the main surface-water influence on ground water in the Fairbanks area alluvial aquifer (Nelson, 1978; Glass and others, in press). Typically, the Tanana River stage rises for one to two weeks during the spring, as a result of snowmelt runoff at lower elevations and ice-jam effects during breakup. A prominent stage increase usually occurs for a longer period during the middle of the summer, in response to snow and glacial runoff from the Alaska Range, 50 mi

Figure 2. University of Alaska Fairbanks study area, with hydrologic data-collection sites.

south of the area shown in figure 2, or from excessive rainfall in the Yukon-Tanana Upland (fig. 3). The Tanana River stage decreases during late summer when temperatures drop in the Alaska Range and high-elevation snow and glacial runoff declines. The stage levels increase after a complete ice layer covers the river, as a result of an increase in flow resistance from the ice cover. Stage levels then decrease throughout the winter because of a continuous reduction in flow (fig. 3).

Figure 3. Stage hydrographs of the Chena River at Fairbanks gaging station and the Tanana River at Fairbanks gaging station for calendar years, 1991 to 1995.

Backwater from the Tanana River as well as variation in flow in the Chena River affects the Chena River stage within the study area. Flow in the Chena River rises during spring snowmelt-runoff and late-summer rainfall-runoff events. Ice also covers most of the Chena River during the winter season, and stages are lower during this time (fig. 3). Deadman Slough enters the Chena River just upstream from the Parks Highway bridge (fig. 2). The culverts at crossings of Deadman Slough under Loftus Street, Fairbanks Street, and Geist Road control the flow through the slough (fig. 2). Backwater effects from the Chena River extend up the slough to the crossing at Geist Road. Water-level data-collection sites north of Geist Road and just south of the Fairbanks Street Bridge are in old slough channels leading to Deadman Slough but are no longer connected to Deadman Slough. Sediments of the Chena Alluvium lie beneath the silty slough deposits.

The Chena River at Fairbanks continuous-record gaging station is located about 0.5 mi downstream from the Steese Highway bridge; the Tanana River at Fairbanks continuous-record gaging station is about 5 mi southwest of the UAF main campus (fig. 1). Data from these sites, located outside the UAF study area, are included for comparison with the hydrographs at the back of this report.

The depth from land surface to ground water is less than 20 ft throughout most of the study area. Ground-water levels respond to changes in stage of the Chena and Tanana Rivers. Pumping at a gravel pit to the east of the study area during the summer of 1992 (fig. 3) caused a drop in ground-water levels during the summer of 1992 and early winter of 1993. The water levels in observation wells during the 1993 and 1994 summer seasons are probably more typical of normal levels.

UAF has two primary water-supply wells (GW1B and GW2) located to the northwest of the Geist Road and Fairbanks Street intersection (fig. 4). A third water-supply well (EW1), located to the south of the UAF power plant and east of the Fairbanks Street Alaska Railroad overpass (fig. 2), provides an emergency back-up water supply. Observation wells are located throughout the study area (figs. 2 and 4). Most of the wells were installed for previous environmental site investigations. Additional observation wells, installed near the primary water-supply wells during the summer and early winter of 1992 and 1994, were used to understand water-supply well pumping effects.

GROUND-WATER SITES

During this study, water levels were measured in a total of 50 wells (figs. 2, 4, and table 1). Most of the wells are relatively shallow—less than 30 ft deep—and screened across the water table in the Chena Alluvium. The water elevation in a well was determined by using either a steel tape and chalk or an electric tape to measure the vertical distance between a measuring point and the water surface. The electric tapes were calibrated against steel tapes and correction factors were applied. Replicate measurements were taken at each well until depth-to-water readings were duplicated within 0.01 ft for measurements made by steel tapes and within 0.02 ft for those made by electric tapes. The measuring points at all wells used in this study were labeled to avoid errors.

The USGS field identification number (field ID) for ground-water sites was assigned on the basis of previous projects and the University's usage of the site. The ground-water site identification (site ID) is based on latitude and longitude and is the primary identifier used in the USGS data base GWSI. The local number is based on the State Rectangular Coordinate System, defined by base and meridian, township, range, section, and quarter section to the fourth order number (fig. 5).

Figure 5. Derivation of local numbers from the official rectangular subdivision of public lands.

SURFACE-WATER SITES

Water elevations were measured at 11 surface-water sites: 2 on the Chena River and 9 on miscellaneous sloughs (figs. 2, 4, and table 2). The USGS operates continuous-record gaging stations on both the Chena and Tanana Rivers. The sloughs act as retention ponds for snowmelt and rainfall runoff. Water elevations at most surface-water sites were determined by reading a staff gage or by using a measuring tape to obtain the distance from the water surface to a point of known elevation. At gaging-station sites, water elevations were determined by using wire-weight gages on bridges or by surveying to the water surface. In the winter, holes were cut through the ice to measure water elevations.

Table 2. Surface-water data-collection sites, University of Alaska Fairbanks area

USGS Field ID	ADAPS Station Number
Sloughs	
CU1	1551401760
CU2	1551401760
CU3	1551401760
CU4	1551401710
CU5	1551401730
CU6	1551401710
CU7	1551401730
RB1	1551401790
RB2	1551401730
Rivers	
Chena River at University Avenue Bridge	15514016
Chena River at Parks Highway Bridge	15514018

The USGS field identification number (field ID) was assigned according to whether the site is a culvert site (CU) or a rebar site (RB), and then numbered chronologically according to the date of its first use. The surface-water station number consists of a two-digit number representing the state, followed by a six-digit number representing the downstream order number. The numbers are not consecutive, thus allowing for new sites to be added in intermediate locations. This information is included in the ADAPS data base.

SURVEY DATA

Elevations of reference points at all water-elevation measuring sites in this study were surveyed to the National Geodetic Vertical Datum of 1929. This datum is called "sea level" in this report. Elevations of all reference points in this study were tied to a reference benchmark (University 2) located near the Duckering Building on the UAF campus. Its elevation is 492.36 ft (U.S. Coast and Geodetic Survey, 1966). The elevations of reference points forming the UAF vertical survey net were connected to the vertical survey net used by the USGS in a study of the Fairbanks International Airport study area, located southwest of the UAF study area (Claar and Lilly, 1995), and to the vertical survey net used by the USGS in a study of the Alaska Railroad Industrial Area located east of the UAF study area (Kriegler and Lilly, 1995; Lilly and others, 1996).

Selected wells were re-surveyed to check and adjust elevations for frost jacking. Frost jacking occurs mainly in late spring or early summer, after the snow has melted. Updated measuring point elevations are applied to water elevations after the estimated time of movement. Horizontal locations of sites were determined by horizontal ground surveys, satellite-based global positioning systems, and from maps of the study area. The horizontal datum for all locations in this report is North American Datum of 1927.

GROUND-WATER AND SURFACE-WATER ELEVATIONS

The remainder of this report consists of a section called "Water-Elevation Tables and Hydrographs." This section presents all the ground-water and surface-water data collected in the UAF area between 1992 and 1995. Data for each site consist of water elevations collected during mass measurements (MM), which are nearly synoptic sets of measurements made once each month at a large group of sites, and partial measurements (PM), which are sets of measurements made as needed at a smaller selection of sites.

Each table showing water levels contains information about the site, well construction, and each measurement made at the site. Land surface (LS) is the average elevation of the ground immediately surrounding the site. The measuring point (MP) is the point of known elevation from which all water-elevation measurements are taken. The error is the difference between replicate measurements made at each well during a given mass or partial measurement.

Hydrographs show all water elevations contained in the corresponding table. Each point on the hydrograph represents a measured water elevation. Uniform time and elevation scales for all hydrographs are used to allow direct comparison between hydrographs. Data points are plotted and connected with lines. These lines show the estimated trends between measurements; however, the connecting lines do not reflect any shorter period stage changes that may have occurred between measurements. No trend lines were drawn between points 2 months or more apart.
