

Geochemical and pellet data of a 8060 foot depth core sample from the  
Tenneco OCS Y-0388-1 (Phoenix) well.

Received 4 December 1989  
Revised 22 February 1990

Total of 3 pages in report

Observed small round translucent pelletoid material in a core chip from 8060' from the Tenneco OCS Y-0338-1 (Phoenix) well.

The translucent pellets did not break down in metholene chlorite, but they did flash under heating.

A chunk of it (small piece of core consisting dominately of pellets) was dissolved in HCl and the following geochemical analysis was done on the residue after the HCl evaporated.

## Qualitative Analysis of Residue

<u>Element</u>	<u>Percent</u>
Calcium	81.5
Phosphorous as P	16.1
Magnesium	0.97
Iron	0.54
Sodium	0.49
Strontium	0.17
Barium	0.06
Zinc	0.04

REMARKS: Sample of white, powdery residue was digested in 20% HCL, and diluted to 10 ml in laboratory pure water. Elemental analysis was performed by inductively coupled plasma (ICP).

RE: OCS-Y-0338 #1 (Phoenix) Core Sample (8060')

Dear John,

The core sample I examined while at the GMC last April 1989 appears to contain numerous megaspores which probably belong to the genus *Tasmanites*. This core sample came from 8060' in the OCS-Y-0338 #1 (Phoenix) well. The age of the rocks would appear to be Early Triassic at that depth, however a slightly younger Middle or Late Triassic age cannot be entirely ruled out.

Sincerely,

Michael B. Mickey
