SUMMARY REFORT OF INVESTIGATIONS IN THE PESERRSURG AND JUNEAU ILINING DISTRICTS AND ITINARAKY OF J. C. ROEFAM, ESSOCIATE WNGINEER TO OCAMISSIONER OF MILNES, TERRITORI $\ddagger$ LEPARTMENT OF LLINES, JUNEAL, ALASKA MAY 12 TO JNNE 3O, INCLUSIVE

May 14-15 - investigation of new aiscoveries made by J. C. B. Hawkes and associates of this year.

A group of 32 lode clatme ware partly staked wiich upon completion will form a rectangular block 3,000 feat in widh and 16 times $600^{\prime}$ In length. This group extends along the east shore of the most northerly peninsula of Kuiu Ialand between Keku Streit and Saginaw Bay. The group lies directly southwest and opposite the Keku Ialands and 5 miles southeast of Point Cornwallis, the most nortierly point of land of Euiu Islend.

The locators of this group are I. M. Hofstai, Lewis Byrdahl, Helen Hawkea, Eilda Dyrdabl and A. C. Hofstad.

The formeticas oovered by this group of clatms consist of andesitic lavas overlain by limestone of lower Parmian age, green -.... agglomerates and greanish basaltic lavas. These lay as bedded formations
$x$ in a small synclinal structure wich is a part of the Kuiu anticlinorium. The general strike of the formations is 30 to $40^{\circ}$ west with flat dips tc the northeast. Folaing with a developed schistosity is efldent in the sto日p ravines at the heads of the small creeks.
\%…
A strata of limestone parallels the beach line and is situated approximately 600 feet back from the beach at ar elevation of 100 . This strata strikes $\mathrm{N} .45^{\circ} \mathrm{W}$. and dips $31^{\circ} \mathrm{NE}$. It is overlain wife greenstone calcaraous conglomerate and underlatn with ar andesitsc lava.

The discovery of a silver-bearing galena and supposedly cobalt and nickel mineral associates was made alongside a suall creek 600 foet from the beach on the No. 9 cleim of the Kpku eroup in the limestone. The limestone outcrops along the south bank of the craek and orosses with an exposure of 150 to 200 feet. Galena is found disseninated through the limeatone in gmall minute fractures and 88 a partial replacement. The greatest amount is near the upper contact whth the greenstone conglomerate in the first 3 feet of limestone, gradually becoming less toward the footwall or bottom. Associated with the galana is $\operatorname{silver,~pyrite~and~possibly~other~metellics.~To~date~only~}$ returns of gold, silver and lead have been recoived which varied from trace of gold to .07 oz . per ton; 9.2 oz . Eilver to $0.6 \mathrm{oz}$. lead 6.3\% to less then $\frac{1}{4} \%$. Returns of cobalt, nickel and manganese were not rsceived. Whether or not these metals exist can only be determined by assay or analysis, as they are not apparent to the eye.

A small sketch was made of this showing.

May 16 - return to Juneau aboard Ms. Dart.

May 17 - office
May 18 - trip to Auks Bay and investigation of Berg and Spaulding properties. Snow encountered on Spaulding property.

May 19 - office
Way 20 - trip to Auk Bey and investigated lower Berg property with John Berg.

May 21 - trip to Olsen's, Mile 26, Glacier Highway, regarding information concerning Paterson property.

Nay 22 - office
May 23 - Sunday at home
Kay 24-25 - sampled Yellowstone tunnel on Berg property. $k x-1+2-53$ This was formerly the Tull \& Stephens prospect and a short report is given in U. S. G. S. Bull. 502, "The Eagle River Region" by Adolph Knopf, page 58. The Yellowstone tunnel hes a length of $110^{\prime}$ driven across the contact of clay slates and brecciated augite melaphyre. Two abort croes-cuts from tunnel on the contact lead in opposite direclions following the hanging wall of the augite melaphyre. Both crosscuts, and from the contact through the brecciated portion of melaphyre and slates to the tunnel portal was channel sampled at 10 feet intervals. This brecciated zone is cemented with quartz that contains sparely distributed arsenopyrite and fine pyrite. The gold appears to be associated with arsenopyrite. A plane table sketch was made of this tunnel and l mediate surface showings.

N后 26 - sampled and mapped tunnels No. $2 \& 3$ of Berg property or Gold King group. These tunnels were driven by the Treadwell Mining Company in 1917, in fractured augite melaphyre on the footwall of the dike that extends northwest of the Dull \& Stephens prospect. These tunnels are located one and 2 half miles via spaulding trail that begins at Mile 13 of the Glacier Highway at an elevation of 620'. They face opposite each other on the bank of a small creek. No. 2 tunnel on the south side has a length of $120^{\prime}$ with a 79' crosscut to the east. The tunnel and crosscut are wholly within the augite melaphyre and the crosscut follows a cross vein that outcrops on the surface a few feet above. In the crosscut the vein carries $4^{\prime \prime}$ to $18^{\prime \prime}$ of quartz and is exposed the length of the crosscut. On the surface this vein contains 2 to 3 feet of quartz. The mineralization 1 s sparse and consists of arsenopyrite and pyrite. This vein was ampled at 10 feet intervals.

The surface exposure was not in condition to sample.
No. 3 tunnel, opposite No. 2, has a length of 1821 and an $80^{\prime}$ crosscut to SW. and a $35^{\prime}$ crosscut to E . The tunnel cuts from augite melaphyre at the portal across the footwall contact into graywacke and ends in slate following a quartz vain for a distance of 80 feet on its northern extremity. The two crosscuts follow a cross vein from the melaphyre into the graywacke and slate to the west. Several cross stringers occur in the fractured melaphyre and some have a width as great as 12 inches. The contact vain varies from $18^{\prime \prime}$ to $4^{\prime}$ and the cross vein varies from a few inches to 18 inches. This cross vein on the surface has a width from 2 to 4 feet of quartz. These veins were sampled at 10 intervals.

Plane table sketches were mede of these tunnels and surface cuts north to the end of the property or No. 4 tunnel, approximately $800^{\text {, }}$ north. This tunnel is on the furtherest north cleim:of:the Berg property and also on the furtherest south claim of the Auk group owned by Spaulding and associates.

May 27-28. No. 4 tunnel is a crosscut tunnel with a length of 110 feet and a crosscut following the augite melaphyre contact for a distance of 34 feet. Several gash veins and veinlet occur both in the melaphyre and slate and a 12 to $18^{n}$ quartz vein follows the contact in the crosscut. This tunnel was sampled at $20^{\circ}$ intervals.

Arthur Thane assisted in sampling and mapping this property, dates May 24 to 28 , inclusive, or 5 days. A wage of six dollars per day was given.

May 29-31 - revisit to Spaulding property, Treasury Hill.
Started mapping. Several cuts fled with snow and was unable to sample. Assessment work started and directed it to cleaning out old cuts at the best showings. Gold knob showings were partly pilled. A return trip is necessary to complete maps and sampling.

June 2-4 - visited the Peterson property located 4 miles east of Mile 26, Glacier Highway, This property of six claims lies
in a northwest-southeast direction paralleling the general structure of the formations. While this property hes had a varied history since its discovery in 1897, and since which time smell amounts of ore have been milled, most of the development work has been done without definite knowledge of the type or structure of the orebody. U. S. G. S. Bull. 502, "The Eagle River Region" by Adolph Knopf, page 53, gives the geology of this property and a short account of the workings. Very little has been done since.

The major showigg on this property is located on the Preirie claim and consists of an apex of smell anticlinal fold in slate between a diorite dike end a dike of augite melaphyre. Both the crest and limbs of the fold contain a compound vein or in geological toms a smell sadde reef. This gives the appearence of a very flat vein and has no doubt been one of the major obstacles that has held back the development of this property. Considerable of the apex of this oredody has been mined for ore by Peterson. The fold appears to be plunging southast at e very low angle and strikes with the general structure of the area. Detall mapping and a study of structure in this aroa would no doubt reveal some interesting poselbilitios on this property and surrounding region.

With the incline shaft filled with water, and several of the oid workings caved, some information was not obtainable. Hovever, two plane table sketohes were made, several samplas were taken, all of which will make for an interestine report. Twenty-three samples were taken.

June 5-9 - office.
June 10 - The Josie and Karen claims located one and a quarter miles northwest of Douglas were visited with fre. Paykull. These two claims are the reataking of Jumbo and Jumbo No. 1 claims of the Dougias Mining Company. These claims are staked upon the andesitic greenstone that extends in a northwest-southeast direction and above the old Treadwell ditoh. They further include the laree slide and the old tunnel of the Douglas Mining Compeny. The tunnel which crosscuts this band of greenstone contains small quarti stringers and veinlets. The walls of the greenstone are cley slateb. This is the same band of greenstone as on the Lianning property to the south. Low gold velues were reported in this tunnel and the owners Papkull and Kilburn want an average assay. The entire tunnel was sampled and one sketch raade.

Visted further discovertes on the Black Beer group, or Manm nins property, adjolning the Josie and Karen claims on the southeast. These discoveries amount to uncovering further this greenstone in which free gold is supposediy seen. One channel sample wes taken and also a sample of float found.

June 11-13 - Returned to Treasury H111 and Gold Knob prospacts. These prospects were located as the Auke group of six olaims by Vic Spaulding in 1935. This property extends from the No. 4 tunnel of the Berg property northwest six claim lengths. A return to this property was nedessary to obtaiz further samples from cleanad cuts.

The geology of these prospecte is giver in Bull, 502, "Eagle River Region ${ }^{n}$ by Adolph Knopf, pp. 55-58, The Golden Knob prospect is a flat quartz vein exposed over $200^{\prime}$ in a long trench. Thie voin has an apparent width of 4 feet, however, there has not been sufficient work done to determine the structure of the orebody. Free gold shows showings of glaartz are ehown in oid trenches in the irmediate vicinity and some show free gold. A 700 foot tunnel driven below these surface showinge was entirely in slate except 60 feet of diorite porphyry at the portal. This tunnel contains nothing of apparent value, having fallen short of the major showings. A sketch was made of this tunnel and surface showings. Four channel samples of the vein were taken.

Treasury Hill prospect is an apparent fractured dike of grayish green color and unidentifled nature whioh contains numerous quartz veins cutting transversely to the strike of the dike. They range in width from a few inches to severel feet and are exposed a distance of $1200^{\prime}$ along the northwest course of the dike. Numerous trenches and rock outs and two short tunnels represent the extent of workings. These wars mapped and seven channel samples were taken from cleaned cuts.

June 15-17 - Visited the Smith and Ashby-Tarro properties at the head of Montana and Windfall besine.

The Solth property at the head of Montana is known as the Patton claim whici contains a small banded cross-vain in altered goh1st. Attempts to operate a small Gibson mill were apperently unsuccessful two years agc. Some stoping and further development wes done in the old worisings. A degcription of the vein is given in Bull. 502, p. 55.
$N$ A sketch was made of this tunnel.
The Asty-T-Tarro property is re-staking of the Smith-Heid property, describeä in the above builetin. Severel olaims are includen in this property at the head of Windfall Creak. The interests of these claims are in alspute between Tonj Tarro and the Ashbys, father and son. However, the old showings of Interest are confined to the Tunnel No. I olaini, staked by Tony Tarro. Mr. F. A. Boyle is interested with Tarro In these claims. Tarro takes the Ashbys in as apparent partners and several claims are staked. The Ashbys are engaged in sluicing the tops of the orebodies and recovering some gold on the tunnel No. l claim. This consists of cutting lerge trenches which is to be recorded as assessment work and without the ald of Tarro, whose help is apparently not wantod.

It was my advice to Sin . Boyle to finance Tarro to the extent of doing sufficient assessment to hold the four original claime. Also directed the work to drifting on the contact of the slate and graywacke-schists with the altered greenstone schist on which the orem bodies apparently lie. Sketches were made of the tunnel and surface ehowings, which judging from the amount of freo gold seen in the pennings and the quartz of the outcrops, this property has some merit end warrants further davelopmant. Nine channel samples were taken.

Tibe trail up Montena Creek to Windfall is washed out in alght places which in four places necessitate oither wading or climbing over ; steep bluffs. Periods of high water do not permit wading. The road is extended two miles, the first mile is filled and graveled to acrcss Montana Creek and the remaining tile is oaterpillar road. Apparently no work is being done this summer.

June 2l-28-At the request of Mr. Pond and Mr. Harrison for a map of the showings and representative semples of the californiaA Golo Steidard group, a trip was made to Berners Bay. It was intended to reach the Kangington and other properties on Berners Bay, however, stormy weather both delayed mapping and reachine the northwest side of Berners Bay. The yinter and Poyd property was completed and the yussie and Thompgon property on Savmill Creak was vialted.

A new discovery has been made on the Finter and Pond property, which is en apparent extension of the old veins acroos a ravine. The best ghowing of these consists of 6 to 20 inches of banded quartz in sohisted augite melephyre exposed along the side of a rock knob for 50 feet. This quartz is well mineralized with arsenopyrite and no doubt coontains good values. Assegsinent work has been conixned to this new discovery and to cleaning out the old workings as mentioned in Bull. 502, pr. 45-47. All showings were mapped and saven chamel semples were taken.

The Bonanza lode group of six claims is a restaking of the

$$
k x-112 \cdot 22
$$ old Tacoma group on the south gide of Sawnill oreek, one and quarter miles from tidewater. A short description of the showings of this group is given in Bull. 642, "Mineral Resources of flaske, 1915" p. 78. Only a small amount of work has bsen done on this property since the above report has been made. Tins bas consisted of a cut along the south bank of a small strean across several feet of augite melaphyre and across the cortact lato slates. Severel small veins cut nearly at right anglea to the strike of the melaphyre alke. These show a pyrite mineralizetion only. A strong stringer zone shows alone the contact in the slates. The showhags on this group show close contact to some intrusive and some

1 carry a good character of ore with a different mineralization thar the Winter and Pond property to the south. I recomended much mors pros. pecting alone the contacts as this section has many interesting features, Three tunnels and some of the opencuts were sampled.

A trip was made to examine a mineralize schist showing two and a half miles south of the head of Echo Cove. Minis mineralized zone is 30 feat wide and contained only pale pyrite along the seams.

June z9-30 = Tried to plan a trip into Carlson Ora Mas unable to contact any one who knew the trail as some of the owners were on the ground doing assessment work and not expected out until July 3.

Considerable rain in the last two weeks has gendered plane table work considerably, of the eleven properties examined, nine wars examined and sampled extensively. A total of 118 samples mere taken and 15 plane table plates were made.

July $\%$ - On this date at 5 abm. an explosive acciant occurred on No. 3 Level, No. 6 Cone of the Alaska Juneau Mine. Only one man was injured and apparently not seriously as he only reported at tho Hospital for one bandage. Two others escaped with only a shaking up. This axplosion was not reported and not known until July 3 at which tine Mr. Humphrey contacted one of the adjoining bulldozers, to whom I am indebted for this information.
sticks of $40 \%$ DuPont Firtra dynamite and want into the next chamber where the other bulldozer was. He went there to go to a light as his own lamp fell down the chute when he lit the shot. (Another cases where Solootric op lamps are safar) When the shot went off there was an immediate explosion of about 100 sticks of the same explosive on the powder bench in the drift off the bulldoze chamber. Porter and the other bulldozer, Geo. Bank, were knocked down, but were lIttle injured except for mall particles and splinters hinting then. The expmesion in the chamber of the pressure of the explosion probably saved then as they were only about 35 feet from the bench. Another man. Hens Johnson, was about $B 5$ feet dow the drift from the bench and was severely bruised. shaken. and cut on the head when he was thrown against a valve on the air line on the floor. A 4-inch air line was broken and the water pipe alongside it.

The powder bench was a plank bench where the explosives were rept for blasting in the chamber and the charges made up. The primers were. In a compartment (No. 6 DuPont blasting caps on 2-foot lengths of fuse), although one or two might have been in the open or exposed to flying fragments from the blast. This chamber was so located that rooks from blasting would be able to hit the bench. The bench was old and old powder bores were around it. There was then a possibility that explosive material from making up charges over a long period had been left on the planks. It was stated that the explosion at the bench occurred almost at the same the the other blast wart off."

After talking this over whth both Br. Humphrey and Mr. Gallom more, a trip into the mine would not have gained much more addietonal information. Kr. Gallemore promead to reveal further information 19 it is gained. Upon the nert trip into the mine I would rocomend seaing tita chamber and powder bench. The bench has already been moved to a crosscut, and several new bench tops are belng ingtalled, pr. Gallamore states. Since this was prior to the firet ald training wash is belng put on with 110 interest, the injuries happily were not serious, Mr. Gallemore's information checked. Wh th Mr. Sumphrey'e, I ooncluded a trip at this time was not warranted.

July 5 - A well managed first ald contest was held in the Fair Buildiag by the dlagka Juneau Mine. Kr. R. I. Stewart and myself acted an judgea as representatives of the offioe.

July 6 - Expect to leave for Goodnews Bay and the most of the Last woak has been in preparation along with some time given to contest. When completed at Coodnews I will wire you for further instructions uniess otherwise informed.
J. C. ROESHM, Associate Mining Enginear.
