FLOODS FROM SMALL DRAINAGE BASINS IN ALASKA

A Compilation of Peak Flow Data
May 1963 to September 1981

By Stanley H. Jones

ABSTRACT

Flood peak stage and discharge data collected since 1963 for small drainage areas in Alaska are compiled. A small-streams flood investigations program was started in 1963 to investigate the magnitude and frequency of floods from drainage basins generally less than 100 square miles in area. Currently (1983), data are being collected at 64 crest-stage gages and 3 continuous-recording gages.

INTRODUCTION

In Alaska, as in many other States, the U.S. Geological Survey historically has concentrated its streamflow data-collection efforts on large drainage basins. Thus very little information was available for basins smaller than about 100 mi². Highways commonly cross many small drainage basins, and information on the flow characteristics--particularly flood or peak flows--of the streams in those basins is critical to the safe and economical design of highway drainage structures. One of the first considerations in the design of hydraulic structures is the magnitude of the design flood. In selecting the design discharge a frequency analysis of a long-term record of floods that have occurred at or near the proposed site is essential.

To fill this data and information need in Alaska, a small-stream investigation program was designed to provide flood data on streams whose drainage areas generally are less than 100 mi². The objective of the program was to obtain sufficient flood data to define the magnitude and frequency of floods on small streams on a regional basis throughout the State and to provide information for detailed hydrologic studies. To date, this effort has been concentrated along routes of existing roads.

The small-streams flood-investigations program in Alaska was initiated in September 1962 under a cooperative agreement between the Alaska Department of Transportation, the Federal Highway Administration, and the U.S. Geological Survey. The present cooperative agreement is between the Alaska Department of Transportation and Public Facilities and the U.S. Geological Survey. To accelerate the program on national forest lands in Alaska, the U.S. Forest Service also has provided funds since 1963.

This report has been prepared to inform the cooperators of the status of the program and to make available in one publication the hydrologic data collected since the 1963 water year. This report updates an earlier compilation (Jones, 1973) that included data collected prior to the 1973 water year and details of the operation of the program.

DESCRIPTION OF PROGRAM

The data-collection network of the small-streams program is designed to sample basins with drainage areas from about 1 to 100 mi² with a variety of physiographic and climatic conditions. Data have been collected at approximately 125 sites since the program began in 1962 (plate 1); 64 crest-stage gages and 3 continuous-recording gaging stations are currently (1983) being operated. A summary of the data included in this report is grouped according to subregions and separated into mountains, plateaus, and lowlands and by drainage area size range within each physiographic classification (table 1).

Periodically, the entire network is evaluated; the data from crest-stage gages, for which 10 years of flood-peak data are available, are analyzed to determine if data collection should be continued at these stations. Stations are continued that are in hydrologically representative basins of the region they are sampling and have hydraulic conditions judged suitable for determining peak discharges. Hydraulically "unsuitable" sites are discontinued and the gages are moved to areas or basins that have not been sampled. For historic floods, the peak stage and the peak discharge are determined at the discontinued gages as well as the current stations.

Data Collection

Hydrologic data obtained in this program consist primarily of the annual maximum instantaneous stages and discharges (table 2). The annual peak values are determined on a water-year basis. (The water year is the 12-month period ending September 30 of the stated year.) Records from the continuous-record stations are used to construct discharge hydrographs for flood periods and to compute the total volume of flood runoff.

Other types of information collected under the small-streams program include:

1. Observations of the formation and effects of aufeis (icings) and of breakup phenomena (melting and disintegration of winter ice cover and erosion and backwater caused by the ice).
2. Observations of the effects of floods in areas where little or no other hydrologic data are available.
3. Documentation (surveying) of flood profiles and channel cross sections and evaluation of channel roughness coefficients. These data are used in the computation of peak discharge values of the gage sites.

Application of Data

Analyses of peak discharge data for Alaskan streams have been presented in the following reports: "Magnitude and frequency of floods in Alaska south of the Yukon River," by Berwick and others (1964); "Flood frequency in Alaska," by Childers (1970); and "Flood characteristics of Alaskan streams," by Lamke (1978). Only Lamke's report, a flood-magnitude and frequency analysis of all peak discharge records of five or more years of flood records through 1975, includes much data or analysis from the stations operated in the small-streams network.

Eleven topographic and climatic factors were computed for each station and used in the analyses. Description of these basin characteristics is presented elsewhere in this report. The resulting flood peaks of 1.25-, 2-, 5-, 10-, 25-, and 50-year recurrence intervals were regionalized by computing a multiple-regression relation using the six characteristic floods as a function of the basin characteristics of the individual basins. Results of the regionalization analysis are a set of equations for estimating flood magnitudes at selected frequencies for ungaged locations within the area represented by the peak discharge data. The six additional years of data (1976-1981) now available could be used to update and refine the regression equations developed by Lamke (1978).

Lamke's statistical analyses and a review of peak-flow data and the distribution of data-collection sites operated in the small-streams program indicate the following:

1. Flood characteristics can be reliably determined in the Southeast and most of the South-central subregions and in the upstream part of the Yukon subregion. Enough data are available for those subregions to provide acceptable standard errors of estimate and to adequately regionalize skew coefficients. Peak discharge data for the Southwest, Northwest, and Arctic Slope subregions provide only a small sample (few, widely-spaced gages) over a short period of record (generally less than 10 years) and thus do not permit very reliable estimates of flood magnitudes and frequencies.
2. Additional flood data are needed in western Alaska, where, except for parts of the South-central subregion and the Tanana River Basin, vast areas are presently ungaged.

Other basin characteristics which affect the magnitude of floods but have not been evaluated on a systematic basis are the nature of the surficial geologic materials and the amount of permafrost in the drainage area. Another factor which should be evaluated is channel geometry. Because a stream channel is shaped by processes that are related to the amount of distribution of streamflow, measurements of the stream channel may provide indices for determining flood-flow characteristics at ungaged sites. The pertinent channel properties are bankfull or main-channel flow width and the mean depth of the main channel associated with this width. The concept of bankfull-channel dimensions has been used in other studies of channel geometry in Alaska (Emmett, 1972; Childers, 1974; Childers and Kernodle, 1981; Childers and others, 1977, 1979). Emmett defines bankfull stage at the stage at which the channel just begins to overflow the flood plain. Childers and Kernodle (1981) determined bankfull elevations by observing the flood-plain surfaces on the edge of the mature flood-plain forest.

Flood Investigations at Miscellaneous Sites

Investigations of indirect measurements of discharge are made for historic or significant floods from small drainage areas even though they occur in basins outside the crest-stage station network. These investigations are undertaken to enhance the flood data base throughout the State. Maximum discharges at such miscellaneous sites are listed in table 3.

PRESENTATION OF DATA

Crest-Stage Station Records

The crest-gage station records are presented in table 2 in the downstream order system used by the U.S. Geological Survey. The records include data from all Geological Survey-operated stations supported by funding from the Alaska Department of Transportation and Public Facilities and the U.S. Forest Service. In addition, data have been included for five crest-stage gage stations which were operated by the Alaska Department of Transportation and Public Facilities.

Annual peak gage heights are not shown if the peak stage did not reach the bottom of the gage or if flooding occurred when the gage was affected by ice. In these cases the annual maximum discharge is estimated. If it is certain that a reasonable estimate for the peak discharge cannot be made, a footnote "unknown" is shown. Gage heights are referred to arbitrary local datum and usually are not referenced to National Geodetic Vertical Datum of 1929.

Discharge Hydrographs

Selected discharge hydrographs for significant floods are presented for recording stations (figs. 1-15) operated on streams with small drainage areas in each of the hydrologic subregions. Floods illustrated were the highest that occurred during the period of recorder operation but are not necessarily the highest for the entire period of data collection at the station. Some of the illustrations are for stations that were not operated under the small-streams flood-investigations program.

Drainage Basin Characteristics

Climatic and physical characteristics of the drainage basins for the stations listed in table 2 are tabulated in table 4. Climatic characteristics were determined from publications cited below and listed in Selected References. Physical characteristics were computed from the latest available U.S. Geological Survey topographic maps. Basin characteristics are defined as follows:

Drainage area--in square miles, is the total drainage area upstream from the gaging station or measurement site. The area is measured in a horizontal plane and is enclosed by a drainage divide.

Main-channel slope--in feet per mile, is the average slope between points 10 percent and 85 percent of the distance along the main stream from the gaging site to the basin divide.

Stream length--in miles, is the length of the main channel between the gaging station and the basin divide measured along the channel that drains the largest basin.

Mean basin elevation--in feet above mean sea level, is the mean elevation of the drainage basin measured by the grid-sampling method from topographic maps. (See details below.)

Area of lakes and ponds--in percent, is the percentage of the total drainage area occupied by lakes and ponds. This is measured by the grid-sampling method from topographic maps having a blue overprint which indicates lakes and ponds.

Areas of forests--in percent, is the percentage of the total drainage area shown as forested on the topographic maps. This is measured by the grid-sampling method from topographic maps having a green overprint which indicates forest cover.

Area of glacier--in percent, is the percentage of the total drainage area shown as glacier on topographic maps. This is measured by the grid-sampling method from topographic maps.

Mean annual precipitation--in inches, as determined from an isohyetal map (National Weather Service, 1972) using the grid-sampling method.

Precipitation intensity--in inches, is the maximum rainfall expected in 24 hours each 2 years as determined from U.S. Weather Bureau Technical Paper 47 (U.S. Weather Bureau, 1963).

Mean annual snowfall--in inches, as determined from an isohyetal map (National Weather Service, 1972) using the grid-sampling method.

Mean minimum January temperature--in degrees Fahrenheit, as determined from an isothermal map (Johnson and Hartman, 1969) using the grid-sampling method.

The grid-sampling method of sampling involves using transparent grids to different map scales in several ways. For determining area, as of ponds, a grid can be laid over a pond and the number of squares and partial squares covering the pond can be totaled and converted to an area, or the number of grid intersections within the area can be multiplied by the area in each square. For determining percentages, as of forested areas or perhaps small ponds if very numerous, the number of grid intersections occurring over forested areas or over water within the basin are counted, multiplied by 100, and divided by the total number of grid intersections within the basin. For determining elevations, temperatures, etc., from a contour map, a reading is taken under each of several grid intersections and the readings are averaged.

Flood Magnitude and Frequency

Flood magnitude and frequency for stations in this report having 10 or more years of record are listed in table 5. Methods described in WRC Bulletin 17B (1981) were used to compute the P_2 , P_5 , P_{10} , P_{25} , and P_{50} flood discharges. Generalized skews as described by Lamke (1978) were used in the computation of the log-Pearson Type III distribution for the stations. Generalized and station skews were weighted according to procedures in WRC Bulletin 17B (1981).

Maximum Known Floods

Maximum known peak discharges for all gaging stations and miscellaneous measurement sites in Alaska are listed in table 3. The maximum discharge in $(\text{ft}^3/\text{s})/\text{mi}^2$ provides an index for comparison of flood peaks between sites. The sites are listed in downstream order and are grouped by WRC subregions.

REPORT LISTS FLOOD DATA FOR ALASKA STREAMS

Data on floods from small drainage basins in Alaska have been compiled in a new report by the U.S. Geological Survey, Department of the Interior. The data were collected under a cooperative study agreement between the Geological Survey, the Alaska Department of the Transportation and Public Facilities, the Federal Highway Administration and the U.S. Forest Service. The study was initiated in 1963 to determine characteristics of floods from drainage areas generally less than 100 square miles. Results of the study, which have many potential applications, have been used primarily in the design of bridges and culverts on highways that cross streams in the small basins.

Data on the peak stage and discharge of floods have been collected for various periods at approximately 125 sites since the study began in 1963. Sixty-four peak-stage gages and 3 continuous recording stations are being operated in 1983.

The 64-page report, "Floods from small drainage basins in Alaska," by Stanley H. Jones, is published as U.S. Geological Survey Open-File Report 83-258. The report may be purchased from Open-File Services Section, Branch of Distribution, Box 25425, Federal Center, Denver, CO 80225. Copies are available for inspection only at Geological Survey offices in Alaska at 1515 E. 13th Avenue, Anchorage, AK 99501; Room 168, 101 12th Avenue, Fairbanks, AK 99701; and Room 441, 710 W. 9th Avenue, Juneau, AK 99801, at the Public Inquiries Offices at 108 Skyline Building, 508 2nd Avenue, Anchorage, AK 99501; 7638 Federal Building, 300 North Los Angeles Street, Los Angeles, CA 90012; 504 Custom House, 555 Battery Street, San Francisco, CA 94111; 678 Court House, West Riverside Avenue, Spokane, WA 99201; and the Survey libraries at Room 4A100 Serial Records Unit, Reston, VA 22092 and 345 Middlefield Road, Menlo Park, CA 94025.

Footnote explanation

- a At different site and datum
- b Unknown
- c Estimated
- d Greater peak may have occurred after
- e At least this high
- f Ice effect
- g Backwater
- h Gage height from downstream gage
- i Discharge affected by inflow from Sheep Creek
- j Tsunami, caused by earthquake
- k To be determined
- m At crest-stage gage site
- n At different site
- p Maximum evident flood
- < Less than
- * Data collected by Alaska Department of Transportation and Public Facilities

Footnote explanation

* Glacier-dammed lake breakout

* Augmented by release of stored water from unnamed lake after embankment was breached

/ Flood from Sheep Creek overflow August 10, 1971, 39.69 ft, 3,270 ft³/s

a Ice flood evidence
